Abstract:

Tarife für Schaftholz in Rinde und Rundholzsortimente.

Die vorliegenden Tarif-Tabellen basieren auf den Erhebungen des Schweizerischen Landesforstinventars (LFI). In einem methodischen Teil werden die Modellherleitungen erklärt und die Formeln in reproduzierbarer Form dargestellt. Der Tabellenteil enthält für alle Hauptbaumarten und alle Produktionsregionen (Jura, Mittelland, Voralpen, Alpen und Alpensüdseite) einen Schaftholztarif, der das Schaftholzvolumen eines Einzelbaumes und einen Sortimentstarif, der den Volumenanteil eines bestimmten Sortimentes am Schaftholzvolumen schätzt. Die Tarife liefern grossräumig (Produktionsregionen) unverzerrte Resultate.

Tariffs for bole volume over bark and for merchantable assortments.

The tariff tables presented here are based on the measurements of the National Forest Inventory (NFI). In the methodical section model derivations are explained and the formulas are presented in a reproducible manner. The table section contains tariffs for each main species and for each productive region (Jura, Plateau, Prealps, Alps, Southern Alps) for the bole volume and for proportions of merchantable timber. The tariffs give unbiased results for large regions (productive regions).

Keywords:: Einzelbaumvolumina, Tariffunktionen, handelsgebräuchliche Sortimente
Keywords: Single tree volume estimation, tariff functions, merchantable assortments

1 Einleitung

Die beiden Erhebungen des Schweizerischen Landesforstinventars LFI von 1983-1985 und 1993-1995, welche sich auf einem systematischen Probeflächennetz über den gesamten Schweizer Wald erstreckten, lieferten u.a. umfangreiche Grundlagendaten für die Schätzung von Einzelbaumvolumina. Das Datenmaterial des LFI ist repräsentativ für die ganze Schweiz. Die daraus hergeleiteten Tarif-Funktionen liefern für alle Hauptbaumarten grossräumig, d.h. für die Produktionsregionen Jura, Mittelland, Voralpen, Alpen und Alpensüdseite, unverzerrte Ergebnisse. Sie sind für zuverlässige Schätzungen von Vorrat, Zuwachs und Nutzung unentbehrlich.

Die hier präsentierten Tariftabellen für Schaftholzvolumina (in Rinde) sind mit der Tariffunktion erzeugt worden, die für LFI-Auswertungen entwickelt wurde. Die Formel wird hier im Detail erläutert. Diese Angaben sind ausreichend, um die Tabellen zu reproduzieren. Die Tabellen enthalten Tariffreihen für die Hauptbaumarten in den fünf Produktionsregionen, für verschiedene Standortgüteklassen, Höhenstufen und Entwicklungsstufen eines Bestandes. Diese Tabellen sollen einerseits einen Vergleich mit kantonalen oder lokalen Tarifen ermöglichen, die zur Zeit in Regional- oder Betriebsinventuren in Gebrauch sind. Andererseits soll man die hier aufgeführten Tariffreihen direkt anwenden oder dann die Tarifformel selbst benutzen können. In der Praxis sind die dazu benötigten Einflussgrössen oft nicht detailliert oder gar nicht vorhanden. In diesen Fällen ist es auch zulässig, diese Formel zu vereinfachen, indem man einzelne Einflussgrössen in grobe Klassen einteilt oder sie konstant hält.

Es kann nützlich sein, wenn man sich bei der Planung von Holzschlägen ein Bild nicht nur über die Durchmesser- und Höhenverteilung der angezeichneten Bäume, sondern auch über den zu erwartenden Sortimentenanfall machen kann. Im Waldentwicklungs-Prognosemodell des LFI werden Sortimentanfänge mit Hilfe sogenannter Sortimentstarife geschätzt. Diese Art von Tarifen schätzt einen Volumenanteil eines bestimmten Sortimentes gemessen am gesamten Schaftholzvolumen von Bäumen. Diese Sortimentstarife sind neu entwickelt worden. Sie entsprechen nun den seit dem 1.1.2000 gültigen Sortierungsvorschriften. Die verwendete Formel wird hier ebenfalls in reproduzierbarer Form dargestellt. Die Prozentzahlen, welche diese Tarife liefern, gelten jeweils für eine bestimmte Anzahl von Bäumen mit gleichem Durchmesser.

2 Datengrundlage

Die vorliegenden Tarif-Tabellen basieren auf Messungen des ersten Landesforstinventars LFI1 (1983-1985). Die Unterschiede zwischen den Tarifen, die dem Zustand LFI1 angepasst sind und denjenigen, die dem Zustand LFI2 (1993-1995) entsprechen, sind nicht bedeutend. Die Werte der LFI2-Tarife liegen i.a. geringfügig höher, die Gründe dafür sind bislang nicht untersucht. Der terrestrische Stichprobenumfang des LFI1 war wesentlich grösser als derjenige des LFI2, so dass aus dem LFI1 beträchtlich mehr Probebäume zur Verfügung stehen und die Funktionen besser abgestützt werden können. Die terrestrische Stichprobe LFI1 bestand aus rund 11'000 Probeflächen, die in einem systematischen Netz von 1x1 km über das ganze Land verteilt waren. Für die Entwicklung von Tarif-Funktionen wurden an durchschnittlich 4 Bäumen pro Probefläche die notwendigen Messungen vorgenommen.

Die Herleitung der Tarife erfolgte in mehreren Schritten. Es wurden dazu verschiedene Datengrundlagen verwendet. Zur Herleitung von Volumen- und Schaftformfunktionen dienten die im Rahmen der waldwachstumskundlichen Forschung der WSL während Jahrzehnten liegend sektionsweise vermessenen Probebäume. Dieser Datensatz umfasst ca. 38'000 Bäume. Er wurde ergänzt durch stehend sektionsweise Vermessungen an weiteren 500 Bäumen mit extremen Formquotienten ($d7/BHD$) und Schlankheitsgraden (h/BHD), so dass die Funktionen in den Randbereichen des Formenspektrums besser abgestützt werden konnten. Die Volumen-, bzw. Schaftformfunktionen (Kaufmann 1993) schätzen ein Schaftholzvolumen, bzw. den Verlauf einer Schaftkurve mit Hilfe des Brusthöhendurchmessers (BHD), des Durchmessers auf 7 m Höhe ($d7$) und der Baumhöhe (h).

Die für die Volumenfunktionen benötigten Eingangsgrössen BHD, $d7$ und h wurden im Landesforstinventar (LFI) an einer Unterstichprobe der Probebäume, den sogenannten Tarifprobepflanzen, erhoben. Im ersten LFI umfasste diese Stichprobe 45000 Bäume. Mit Hilfe des mit einer Volumenfunktion geschätzten Schaftholzvolumens dieser Bäume wurden Tarife entwickelt, welche das Volumen in Abhängigkeit des BHD schätzen. Als weitere Einflussgrössen in den Tarif-Funktionen wurden gutachtlich beurteilte Einzelbaummerkmale sowie Standorts- und Bestockungsmerkmale verwendet, welche zusätzlich zum BHD einen Einfluss auf das Baumvolumen haben.

Zur Herleitung der Sortimentstarife dienten ebenfalls die LFI1-Tarifprobebäume. Mit Hilfe der Eingangsgrößen BHD, d_7 und h wurden Schaftholz-Kurvenverläufe gerechnet. Damit war es möglich, jeden einzelnen Baumschaft in handelsgebräuchliche Sortimente (WVS, SHIV, VSRH 1999) zu zerlegen. Daraus liessen sich Sortimentstarife ableiten, welche den Volumenanteil eines bestimmten Sortimentes (ohne Rinde) am Schaftholzvolumen (in Rinde) schätzen.

3 Methoden

3.1 Schätzung des Schaftholzvolumens in Rinde

Das Grundmodell für die Schaftholz-Tarife ist eine Exponentialfunktion, wie sie ähnlich schon von Hoffmann (1982) und Winzler (1986) für Tarifierleitungen verwendet worden war. Die im folgenden dargestellte Funktion wurde für die Auswertung des zweiten LFI neu entwickelt (Kaufmann 1996, Kaufmann 1999 a). Die Stratifizierung des Datenmaterials nach Hauptbaumarten und Produktionsregionen sowie die Auswahl von Einflussgrößen für die Funktionen wurden mit Hilfe von Kovarianzanalysen vorgenommen. Daraus resultierte das folgende Tarif-Modell:

$$V_k = e^{(b_{0k} + b_{1k} \cdot \ln(\text{BHD}) + b_{2k} \cdot \ln^4(\text{BHD}) + \sum_{j=3}^7 b_{jk} \cdot B_j)}$$

mit:

V: Schaftholzvolumen in Rinde in m^3
 k: Tarifnummer (201-230, Tab. 1)

b_0 - b_7 : Modellkoeffizienten (Tab. 2)

BHD: Brusthöhendurchmesser in cm

B_3 - B_7 : Einzelbaum-, Bestandes- und Standortsmerkmale:

B_3 : Standortsgüte: Gesamtwuchsleistung (GWL) in kg Trockensubstanz pro Hektare und Jahr

B_4 : d_{dom} : mittlerer BHD der hundert stärksten Bäume pro Hektare in cm, Indikatorgrösse für Entwicklungsstufe

B_5 : Verzwieselung (1: ja / 0: nein)

B_6 : Höhe ü. Meer (m)

B_7 : Schicht eines Baumes (0: Oberschicht / 1: nicht Oberschicht)

Die Koeffizienten b_0 - b_7 wurden mittels nichtlinearer Regression geschätzt (Methode Gauss-Newton mit Verwendung der ersten partiellen Ableitungen der Funktionen nach den Koeffizienten, SAS 1990).

Die Einflussgrößen in den Tariffunktionen sind multiplikativ miteinander verknüpft ($e^{(a+b)} = e^a \cdot e^b$). Als Beispiel dazu ist in Abb. 1 eine Kurvenfächerung in Abhängigkeit des d_{dom} dargestellt. Der d_{dom} ist ein Mass für die Entwicklungsstufe des Bestandes (Zingg und Bachofen, 1988). Tarifkurven verlagern sich mit zunehmender Entwicklungsstufe, d.h. ein Baum mit gleichem BHD hat in einer höheren Entwicklungsstufe ein grösseres Volumen als in einer tieferen (Pardé und Bouchon, 1988). Abb. 1 zeigt die Verlagerung der Tarifkurven in Abhängigkeit der Entwicklungsstufe des Bestandes, in welchem sich ein Baum befindet.

Abb. 1: Verlagerung von Tarifkurven in Abhängigkeit des d_{dom} .
 Baumart Fichte, Produktionsregion Alpen, mässige Standortsgüte (Gesamtwuchsleistung von 2250 kg Trockensubstanz pro ha u. Jahr), montane Höhenstufe (1000m ü.M.).

Die Tariffunktionen mit $b_2 < 0$ (siehe Tab. 2) haben einen Wendepunkt (in Abb. 1 bei BHD=65 cm). Dieser liegt am Kulminationspunkt der Volumenzunahme bei zunehmendem BHD. Ein Wendepunkt kommt dadurch zustande, dass das Höhenwachstum eines Einzelbaumes lange vor dem BHD-Zuwachs kulminiert und Bäume mit sehr grossen BHD durchschnittlich geringere Formquotienten (d_7/BHD) aufweisen als die übrigen. Ein Wendepunkt verhindert, dass Volumina in einem Extrapolationsbereich bis ca. 200 cm, in welchem Extremwerte noch vorkommen können, massiv überschätzt werden.

Wie stark die einzelnen Einflussgrössen das Schaftholzvolumen beeinflussen, wird am Beispiel eines Sensitivitätsdiagrammes für die Baumart Fichte (Abb 2.) dargestellt. Das Schaftholzvolumen einer Fichte mit einem bestimmten BHD (20cm, 40cm, 60cm in Abb. 2) ist im Mittelland durchschnittlich grösser als in den andern Regionen. Die Schichtzugehörigkeit eines Baumes (Abb. 2, Säule 5) oder eine Verzweiselung (Abb2., Säule 4) haben einen grösseren Einfluss auf das Volumen als eine BHD-Aenderung von ± 5 cm (Abb. 2, Säule 6). Geringer als der BHD-Einfluss ist hingegen der Einfluss einer Aenderung des d_{dom} um ± 10 cm (Abb. 2,Säule 1), der Standortsgüte um ± 1500 kg Trockensubstanz pro ha u. Jahr (Abb. 2, Säule2) oder der Meereshöhe um ± 500 m (Abb2., Säule 3). Alle Einflüsse nehmen mit zunehmender Baumdimension zu. Die Sensitivität gegenüber den Einflussgrössen ist bei den andern Baumarten ähnlich wie bei der Fichte.

Tab.1: Schafholztarife (Schafholzvolumen in Rinde in m³).

Abb. 2: Sensitivität der Tariffunktion für Baumart Fichte an den Stellen BHD=20 cm, BHD=40 cm und BHD=60 cm.

- Säulen:
- 1: $d_{\text{dom}}=45 (\pm 10)$ cm
 - 2: $\text{GWL } 3750 (\pm 1500)$ kg/(ha*Jahr)
 - 3: Höhe ü.M. 1000 (± 500) m ü.M., Mittelland 500 (± 300) m ü.M.
 - 4: Zwiesel (0,1)
 - 5: Schicht (0,1)
 - 6: BHD 20(± 5) cm, 40(± 5) cm, 60(± 5) cm

3.2 Nutzbare Derbholzmenge

Die nutzbare Derbholzmenge (Durchmessergrenze 7 cm) eines Baumes wird ausgehend von seinem Schaftholzvolumen in Rinde geschätzt. Die Volumenanteile von Schaft- und Astderbholz werden mit Schaftform-, Astderbholz- und Rindenabzugsfunktionen (Kaufmann 1999 a, Altherr et al. 1978) geschätzt. Diese Anteile sind u.a. abhängig vom BHD eines Baumes. Die in Tab. 3 aufgeführten Anteile sind Durchschnittswerte aller Bäume, wie sie anhand der LFI-Einzelbaummessungen zum Zeitpunkt des zweiten LFI festgestellt wurden. Mit der Veränderung der Bestandesstrukturen können sich auch diese Werte wieder ändern.

Tab. 3: Schaftholz-Volumenanteile in Prozenten des Schaftholzes in Rinde

| Hauptbaumart | Schaftholz in Rinde % | Schaftderbholz ohne Rinde, ohne Stock % | Schaft- und Astderbholz ohne Rinde, ohne Stock % |
|--------------|---------------------------------|--|--|
| Fichte | 100 | 86 | 86 |
| Tanne | 100 | 85 | 85 |
| Föhre | 100 | 84 | 85 |
| Lärche | 100 | 74 | 75 |
| Buche | 100 | 89 | 103 |
| Ahorn | 100 | 85 | 91 |
| Esche | 100 | 81 | 89 |
| Eiche | 100 | 78 | 92 |

In einer Wiederholungsinventur auf permanenten Probeflächen kann wohl festgestellt werden, welche Bäume in der Zeit zwischen zwei Inventuren verschwunden sind, vielfach ist es aber nicht eindeutig möglich, festzustellen, ob ein Baum genutzt wurde oder ob er auf natürliche Weise abgegangen ist. Im LFI wurde diese Unterscheidung nur bei denjenigen Probestämmen vorgenommen, bei denen sie zweifelsfrei möglich war (Stierlin et al. 1994). Anhand dieser Unterstichprobe wurden dann die in Tab. 4 dargestellten Werte ermittelt. Diese zeigen den Volumenanteil der tatsächlich verwerteten Bäume zwischen LFI1 und LFI2 an der Gesamtnutzung (Tab.4, Spalte A), welche auch die natürlichen Abgänge enthält.

Der Anteil der nutzbaren Derbholzmenge an der Gesamtnutzung ist der nutzbare Volumenanteil eines Einzelbaumes multipliziert mit der Wahrscheinlichkeit, dass ein Baum auch tatsächlich verwertet wurde (Tab 4. Spalte C). Darin sind keine Abzüge für Holzernteverluste enthalten.

Tab. 4: Anteil verwerteter Bäume an der Gesamtnutzung (A), Anteil Derbholz an Schaftholz in Rinde (B), nutzbare Derbholzmenge (C)

| Region | Anteil verwerteter Bäume an der Gesamtnutzung % | Anteil Derbholz an Schaftholz in Rinde % | Anteil der nutzbaren Derbholzmenge % |
|----------------|--|---|---|
| | A | B | C=A x B |
| Jura | 92 | 89 | 82 |
| Mittelland | 94 | 92 | 86 |
| Voralpen | 84 | 87 | 73 |
| Alpen | 73 | 86 | 63 |
| Alpen-Südseite | 50 | 87 | 44 |
| Schweiz | 86 | 88 | 76 |

3.3 Rundholz-Sortimente

Die logistische Funktion, welche als Modell bei den Sortimentstarifen dient, war in dieser Form von Schmid-Haas (1976) vorgeschlagen worden. Für die Herleitung von Sortimentstarifen ist Voraussetzung, dass einzelne Baumschäfte in handelsübliche Sortimente zerlegt werden können. Dazu ist es erforderlich, den Verlauf eines Baumschaftes mit einer Schaftformfunktion zu beschreiben. Ein Schaftkurvenverlauf kann relativ genau geschätzt werden, wenn der BHD, der d_7 und die Höhe h eines Baumes bekannt sind (Kaufmann 1993, Kaufmann 1999 a). Mit Schaftformfunktionen können Sortimentsvolumen geschätzt werden. Tarife, welche Volumenanteile an bestimmten Sortimenten in Abhängigkeit des BHD schätzen, wurden mit Hilfe der Sortimentsvolumen der LF11-Tarifprobehäuser entwickelt. Die Sortiments-Tariffunktion liefert den Volumenanteil eines Sortiments in einer Sortimentsklasse i oder in einer höheren ($i+$):

$$S_{kai+} = \frac{O_{kai+}}{1 + (q_{kai+} + r_{kai+} \cdot BHD)^{t_{kai+}}}$$

$$S_{kai} = S_{kai+} - S_{ka(i+)+}$$

s: Volumenanteil eines bestimmten Sortimentes (ohne Rinde) am Schaftholz in Rinde.

k: Tarifnummer (Tab. 5)

i: Rundholzklasse

a: Sortierungsart:

- 1= Nadel-Kurzholz
- 2= Nadel-Mittellangholz
- 3= Nadel-Langholz
- 4= Laubrundholz

4 Zusammenfassung

Die hier präsentierten Tabellen enthalten durchmesserabhängige Einzelbaumvolumina und Sortimentsanteile, wie sie im LFI1 (1983-1985) festgestellt wurden. Die Unterschiede zu den entsprechenden Werten im LFI2 (1993-1995) sind gering, der Stichprobenumfang des LFI1 ist aber beträchtlich grösser, so dass die Funktionen mit diesem Datenmaterial besser abgestützt werden konnten. Die verwendeten Formeln sind erläutert, die dazugehörigen Koeffizienten-Tabellen beigelegt, so dass die dargestellten Tarifreihen mit diesen Grundlagen reproduziert werden können. Die vorliegenden Tabellen sollen einerseits einen Vergleich der LFI-Tarife mit kantonalen oder lokalen Tarifen ermöglichen, andererseits sollen passende Tarifreihen entnommen und verwendet werden können. Es soll auch möglich sein, beliebige Tarifreihen mit Hilfe der hier dargestellten Formeln zu erzeugen. Gewisse Wald-Strukturmerkmale wie die Entwicklungsstufe sind bei der Herleitung der Tarife berücksichtigt worden. Andere Merkmale, die das Schaftvolumen ebenfalls beeinflussen wie z.B. der Schlussgrad oder die Anzahl der Baumschichten sind als Einflussgrössen nicht enthalten. Da Tarife von Waldstrukturen abhängig sind, gelten Tarife streng genommen nur für die Population, aus welcher sie stammen und für den Zeitpunkt, zu welchem die Probebaummessungen vorgenommen wurden. Die Daten des LFI repräsentieren den ganzen Schweizer Wald in einem bestimmten Zustand zu einem bestimmten Zeitpunkt. Veränderungen im Wald laufen langsam ab. Die hier präsentierten Tabellen haben heute noch Gültigkeit. Es ist möglich, dass nach Abschluss eines dritten LFI in einigen Jahren Anpassungen notwendig sein werden.

6 Tarif-Tabellen

6.1 Schaftholz in Rinde

Inhalt der Tabellen

Die Tabellen enthalten das Schaftholzvolumen in Rinde in m^3

Für die Tarifnummern 215, 228, 229 und 230 (übrige Nadel- und Laubhölzer) sind keine Tabellen erstellt worden.

Wertebereiche von Einflussgrössen in den Tariffunktionen

| | | | | | | | | |
|------------------------------|-----------|-----------|-----------------------------------|----|----|----|----|----|
| Gesamtwuchsleistung : | gering: | 750-1500 | kg Trockensubstanz pro ha u. Jahr | | | | | |
| | mässig: | 1500-3000 | '' | '' | '' | '' | '' | '' |
| | gut: | 3000-4500 | '' | '' | '' | '' | '' | '' |
| | sehr gut: | über 4500 | '' | '' | '' | '' | '' | '' |

| | | | |
|---------------------------|---------------|-----------|------------|
| Entwicklungsstufe: | Stangenholz: | d_{dom} | 12-30 cm |
| | Baumholz I: | d_{dom} | 30-40 cm |
| | Baumholz II: | d_{dom} | 40-50 |
| | Baumholz III: | d_{dom} | über 50 cm |

Annahmen in den Tabellen

| | | |
|-----------------------------|---------|-----------------------|
| Gesamtwuchsleistung: | gering: | GWL=2000 kg/ha u.Jahr |
| | gut: | GWL=4500 kg/ha u.Jahr |

6. 2 Handelsgebräuchliche Sortimente

Inhalt der Tabellen

Die Tabellen enthalten Volumenanteile ohne Rinde in Prozent des Schaftholzes in Rinde.

Die Anteile gelten jeweils für ein Kollektiv mehrerer Baumschäfte.

Die Dimensions-Sortierung wurde nach den seit 1.1.2000 gültigen Vorschriften (WVS, SHIV und VSRH, 1999) vorgenommen.

Längenklassen des Nadel-Rundholzes

- L1: Kurzholz (4-6 m)
- L2: Mittellangholz (6,5–14,5 m)
- L3: Langholz (mindestens 15 m)

Länge des Laub-Rundholzes

Stücklänge 3-15 m

Sortierung nach Dimensionen

| Klasse | Mittendurchmesser (cm) | minimaler Zopfdurchmesser (cm) des Nadelholzes |
|--------|------------------------|---|
| 1 | 10 – 19 | 10 ¹⁾ |
| 2 | 20 – 29 | 18 |
| 3 | 30 – 39 | 18 |
| 4 | 40 – 49 | 22 |
| 5 | 50-59 | 22 |
| 6 | mindestens 60 | 22 |

1) Abweichung von den Sortierungsvorschriften, welche für die Klasse 1a (Mittendurchmesser 10-14 cm) keinen Zopfdurchmesser und für die Klasse 1b (Mittendurchmesser 15-19 cm) einen minimalen Zopfdurchmesser von 14 cm vorschreiben.
